A simple method for validation and verification of pipettes mounted on automated liquid handlers

Stangegaard M, Hansen AJ, Frøslev TG, Morling N

INTRODUCTION

Automated liquid handlers (ALHs) are increasingly used to improve throughput, pipetting accuracy and prevent occupational injuries to the technical staff due to intensive manual pipetting. Standardized procedures for calibration of standard piston operated pipettes exist and many laboratories calibrate their pipettes with defined intervals. However, less standardized is the routine validation and verification of ALHs, though suggestions to how it should be performed exist. Commercial solutions have also been introduced.

MATERIAL AND METHODS

A 7-step serial dilution of Orange G was prepared manually in quadruplicates in a flat bottom 96-well microtiter plate (BD Falcon) by means of calibrated pipettes (column 9-12). This was used as a standard row. Each pipette of the liquid handler (1 up to 8) dispensed a selected volume (1 to 200μL) of Orange G eight or more times into the wells of the microtiter plate. All wells contained a total of 200μL liquid. The optical density (OD) was read at 490 nm, and the dispensed volume of each pipette was calculated based on a plot of volume and OD of a known set of Orange G dilutions. Finally, the percent inaccuracy (%d) and the imprecision (%CV) of each pipette was calculated.

RESULTS

Using pre-defined acceptance criteria, each pipette on each ALH was then either approved or rejected. Rejected pipettes ... four Biomek 3000 robots.

CONCLUSIONS

We have set up and implemented a simple solution for the continuous verification of pipettes mounted on automated liquid handlers as necessary for accredited work under the international laboratory standard ISO 17025. The method is cheap, simple and easy to use for aqueous solutions, but it requires a spectrophotometer that can read microtiter plates. The method can be used with both disposable tips, fixed tips as well as manual pipetting.
